58I

# Quantitative and Computational skills

58I Lab and Prof Skills II

#### Lecture Overview

Introduction to Q&C skills strand

- Q&C skills strand in 58I
- Data Skills in degree program roadmap

Stage 1 - revision, brief!

Linear models - what are they?

Revisiting t-tests and ANOVA as linear models

Generalised linear models

#### Learning Objectives for 58I as a whole

- 1. To be able to generate a testable hypothesis.
- 2. To design and conduct experiments to test this hypothesis, with appropriate controls.
- 3. To have practical experience of a range of techniques relevant to the discipline.
- 4. To work effectively within a team.
- 5. To be able to write a scientific report based on practical work.
- 6. To communicate scientific information and ideas in the form of a variety of media to a variety of audiences.
- 7. To use appropriate graphical methods to produce data figures with appropriately detailed legends.
- 8. To use relevant statistical or other analytical methods to analyse data.
- 9. To research scientific literature in a given area, and write an extended and well-structured account.

#### Learning Objectives for 58I Q&C

- 1. To be able to generate a testable hypothesis.
- 2. To design and conduct experiments to test this hypothesis, with appropriate controls.
- 3. To have practical experience of a range of techniques relevant to the discipline.
- 4. To work effectively within a team.
- 5. To be able to write a scientific report based on practical work.
- 6. To communicate scientific information and ideas in the form of a variety of media to a variety of audiences.
- 7. To use appropriate graphical methods to produce data figures with appropriately detailed legends.
- 8. To use relevant statistical or other analytical methods to analyse data.
- 9. To research scientific literature in a given area, and write an extended and well-structured account.

#### Assessment

Express competency in Experimental Design and Bioscience Techniques (and elsewhere)

#### **Becoming Competent**

Make it fun. Practice and engage with people.

The workshops are not tests, they are opportunities.

It is expected that you make a lot of mistakes and need help.

Talk to each other, demonstrators and lecturers.

"There are two ways to write error free code and only the third way works"

#### Topics covered in 58I Q&C

Impossible to cover everything to you might ever need!

Different people will use different topics

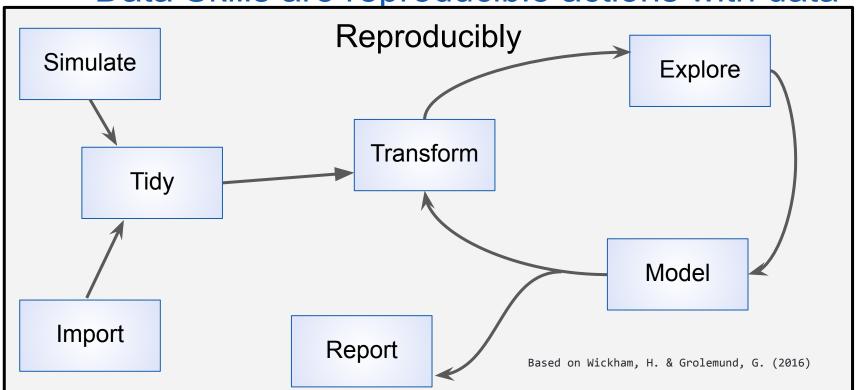

Chosen topics are: foundational, follow stage 1 well, widely applicable (in this module and beyond), transferable conceptually:

- Generalised Linear Models:
- Non-linear Models (non-linear regression)

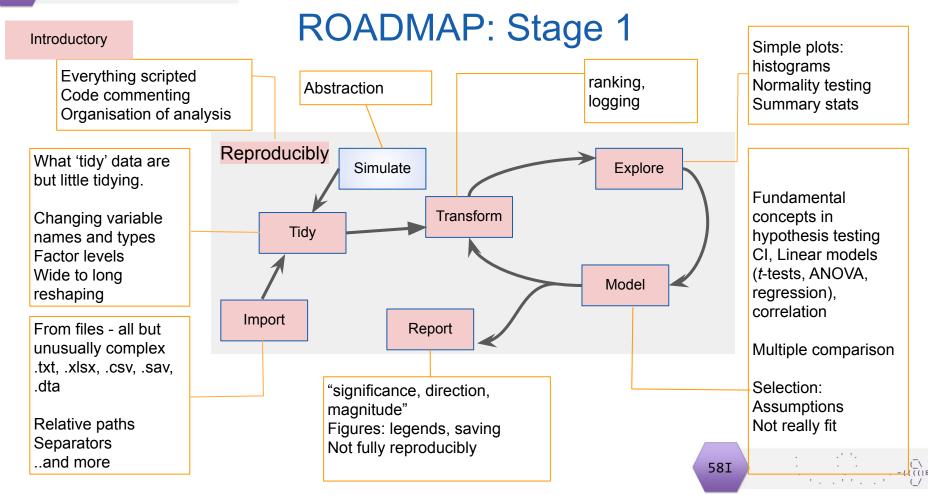

Methods which are very specific to the Experimental Design / Bioscience Technique taken are covered in that option. Talk to your project leader.

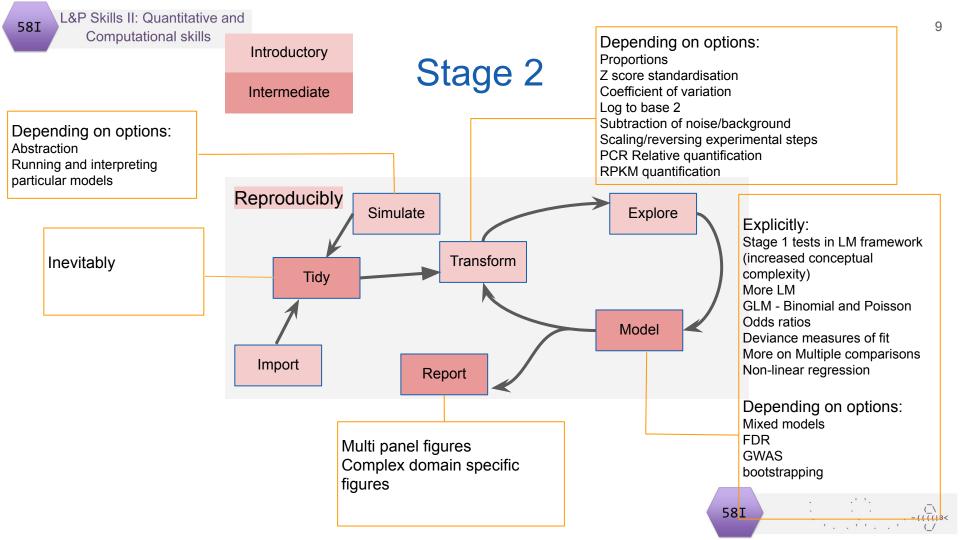

58I

#### Data Skills are reproducible actions with data

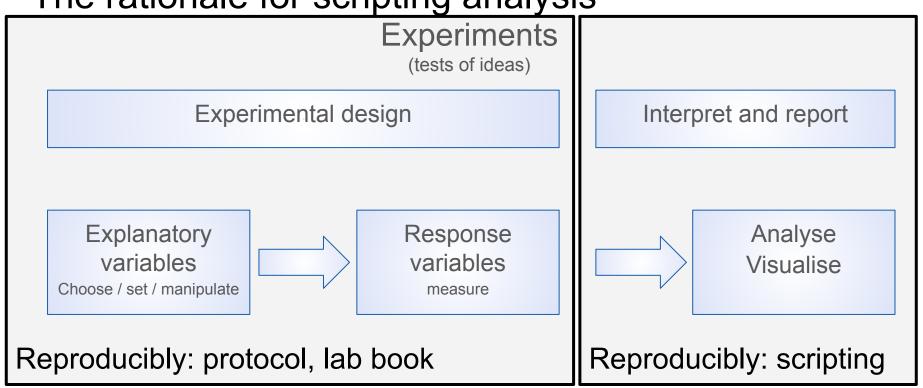

L&P Skills II: Quantitative and Computational skills

The rationale for scripting analysis

#### Why R?

It's a good choice but not the only option.

- R caters to "users who do not see themselves as programmers, but then allows them to slide gradually into programming"
- Community, active, relatively diverse
- Language designed for data analysis and visualisation so makes those easy
- Open source, Free,
- Reproducibility R markdown, R's "killer feature"

# Stage 1 Revision: experiments and analysis

Something we measure

Can be explained by

Some things we control, choose or set

Response variable

Dependent variable The 'v' s Relationship

**Predictor variables** 

Independent variable(s)
The 'x' s

function(y  $\sim x$ ) function(y  $\sim x_1 * x_2$ ) 58I

## Stage 1 Revision: experiments and analysis

Something we measure

Can be explained by

Some things we control, choose or set

Response variable

Normally distributed

Relationship

Linear

**Predictor variables** 

Continuous: regression

Categories: t-test, ANOVA

function(y  $\sim x$ ) function(y  $\sim x_1 * x_2$ )

#### Contact time: 1 lecture + 4 workshops

Lecture 1: Introduction to Generalised Linear Models (ER)

Workshop 1: Linear Models (ER)

T-tests, ANOVA and regression are used when we have a continuous response variable. We revisit these using a linear modelling framework. This means using a single function `lm()` rather than three different ones and enhancing our understanding of the concepts underlying the tests.

Workshop 2: Generalised Linear Models for Poisson distributed data (ER)

Workshop 3: Generalised Linear Models for Binomially distributed data (ER) We extend our knowledge of linear models by considering other types of response variable.

Workshop 4: Non-linear regression and dynamics (JWP)

#### **Lecture Overview**

Introduction to Q&C skills strand

- Q&C skills strand in 58I
- Data Skills in degree program roadmap

Stage 1 - revision, brief!

Linear models - what are they?

Revisiting t-tests and ANOVA as linear models

Generalised linear models

#### Learning objectives

By actively following this lecture and undertaking the exercises in workshop 1 the successful student will be able to:

- Explain the the link between t-tests, ANOVA and regression
- Appropriately apply linear models using lm()
- Interpret the results using summary() and anova() and relate them to the outputs of t.test() and aov()

#### What are linear models?

Something you have already met!

Equation to explain, with a linear relationship, one response variable with one or more explanatory variables:  $y = ax_1 + bx_2 + ....$ 

Procedure	Response	Explanatory	R	Stage 1 examples
Single linear regression	Continuous	1 Continuous	y~x	mand ~ jh mass ~ day
Two-sample t-test	Continuous	1 categorical (2 levels)	y ~ x	adiponectin ~ treatment time ~ status
One-way ANOVA	Continuous	1 categorical (2 or more levels)	y~x	myoglobin ~ species
Two-way ANOVA	Continuous	2 categorical (2 or more levels each)	y~x1*x2	para ~ season * species diameter ~ agent * species

## Key points

T-tests, ANOVA and regression are fundamentally the same, collectively called 'general linear models'. They can be carried out in R with 1m()

There are other linear models too

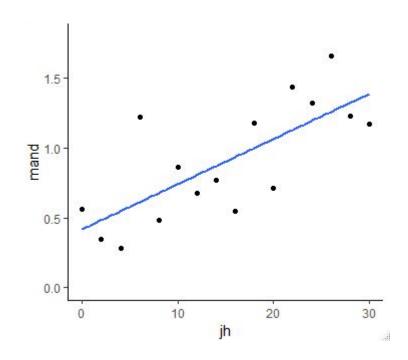

The concept can be extended to 'generalised linear models' for different types of response. Generalised linear models are carried out in R with glm()

The output of lm() looks more complex, at first, than the outputs of t.test() and aov()

The output of glm() is like that for lm(). So we will revisit regression, t-tests and ANOVA using lm() to help you understand the output

Concentration of juvenile hormone (JH) and mandible length in stag beetles

```
mod <- lm(data = stag, mand ~ jh)</pre>
```

```

P value for slope of single variable = P value of whole

P value of whole model

This will not be true for more for i) one-way anova with more than 2 gps ii) two-way anova iii) other linear models

#### Revisiting: two-sample t-test using t.test()

 $t.test(y \sim x, data = mydata, var.equal = T)$ 

Example 1 from 17C.

Is there a significant difference between the masses of male and female chaffinches?

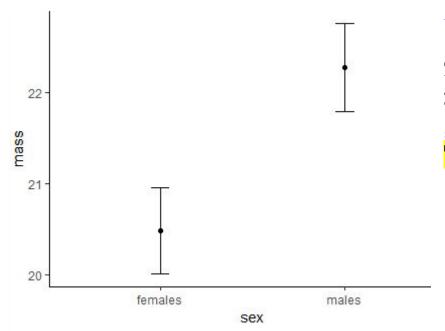

Example 2 from 08C.

Does treatment with Nicotinic acid affect adiponectin secretion compared to control treatment?

```
t.test(mass ~ sex, data = chaff, var.equal = T)
      Two Sample t-test
data: mass by sex
t = -2.6471, df = 38, p-value = 0.01175
alternative hypothesis: true difference in means is not equal to 0
95 percent confidence interval:
 -3.167734 -0.422266
sample estimates:
mean in group females
                      mean in group males
               20,480
                                     22,275
t.test(adiponectin ~ treatment, data = adip, var.equal = T)
       Two Sample t-test
       adiponectin by treatment
t = -3.2728, df = 28, p-value = 0.00283
alternative hypothesis: true difference in means is not equal to 0
95 percent confidence interval:
 -3.1910762 -0.7342571
sample estimates:
  mean in group control mean in group nicotinic
                                       7.508667
               5.546000
```

## Revisiting: two-sample t-test using t.test()

 $t.test(y \sim x, data = mydata, var.equal = T)$ 

The means are significantly different

#### Alternative way to state:

Sex has a significant effect on mass

#### Using t.test

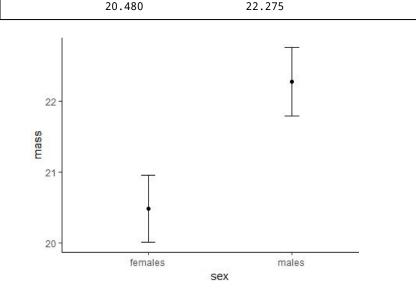

## Revisiting: Comparing t.test() with Im()

```
t.test(mass ~ sex, data = chaff, paired = F, var.equal = T)

    Two Sample t-test
data: mass by sex
t = -2.6471, df = 38, p-value = 0.01175
alternative hypothesis: true difference in means is not equal to 0
95 percent confidence interval:
    -3.167734 -0.422266
sample estimates:
mean in group females mean in group males
```

Output of Im() to do a t-test looks the same as the output of Im() to do a regression.

Mathematically the same thing!

```
mod <- lm(mass ~ sex, data = chaff)</pre>
summary(mod)
Call:
lm(formula = mass ~ sex, data = chaff)
Residuals:
    Min
             10 Median
                                    Max

                         0.4795 42.712
                                          <2e-16 ***
                                                               Difference is
              1.7950
                         0.6781
                                          0.0118 *
sexmales
                                                              significant
Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
Residual standard error: 2.144 on 38 degrees of freedom
Multiple R-squared: 0.1557, Adjusted R-squared: 0.1335
F-statistic: 7.007 on 1 and 38 DF, p-value: 0.01175
```

## L&P Skills II: Quantitative and Computational skills

t.test(mass ~ sex, data = chaff, paired = F, var.equal = T)

#### Using t.test

## Revisiting: Comparing t.test() with Im()

```
Two Sample t-test
                                                                                               Intercept is mean of 'lowest' level of factor
data: mass by sex
t = -2.6471, df = 38, p-value = 0.01175
alternative hypothesis: true difference in means is not equal to 0
                                                                                               I.e., equivalent to x = 0 in regression
95 percent confidence interval:
-3.167734 -0.422266
sample estimates:
mean in group females
                        mean in group males
               20.480
                                     22.275
                                                                                                                                       Using Im()
                                                                     mod <- lm(mass ~ sex, data = chaff)</pre>
                                                                     summary(mod)
                                                                     Call:
                                                                                                                          Female mean sig diff
                                                                     lm(formula = mass ~ sex, data = chaff)
                                                                                                                          from 0. Not important
                                                                     Residuals:
                                                                                  10 Median
                                                                         Min
                                                                                                         Max
                                                                     -5.2750 -1.7000 -0.3775 1.6200 4.1250
                                                                     Coefficients:
                                                                                 Estimate Std. Error t value Pr(>|t|)
                                                                     (Intercept) 20.4800
                                                                                              0.4795 42.712
                                                                                                               <2e-16 **
                                                                     sexmales
                                                                                   1.7950
                                                                                              0.6781
                                                                                                       2.647
                                                                                                               0.0118 *
                                                                     Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

#### Why use Im()?

Extendable! These are particular cases but a linear models include any number of continuous and categorical explanatory variables.

Procedure	Response	Explanatory	R	Stage 1 examples
Single linear regression	Continuous	1 Continuous	y ~ x	mand ~ jh mass ~ day
Two-sample t-test	Continuous	1 categorical (2 levels)	y ~ x	adiponectin ~ treatment time ~ status
One-way ANOVA	Continuous	1 categorical (2 or more levels)	y~x	myoglobin ~ species
Two-way ANOVA	Continuous	2 categorical (2 or more levels each)	y~x1*x2	para ~ season * species diameter ~ agent * species

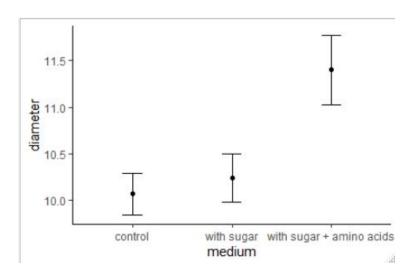

# Why use Im()?

For example...

Procedure	Response	Explanatory	R	Stage 1 examples
Single linear regression	Continuous	1 Continuous	y~x	mand ~ jh mass ~ day
Two-sample t-test	Continuous	1 categorical (2 levels)	y~x	adiponectin ~ treatment time ~ status
One-way ANOVA	Continuous	1 categorical (2 or more levels)	y ~ x	myoglobin ~ species
Two-way ANOVA	Continuous	2 categorical (2 or more levels each)	y~x1*x2	para ~ season * species diameter ~ agent * species
	Continuous	1 categorical and 1 continuous	y ~ x1*x2

```

## Usual steps in applying Im()

anova(mod1)

Test of the 'explanatory power' of the model

For reference: it's also how to compare models

## Usual steps in applying Im()

Post hoc - which means differ

Use glht() from package multcomp

Torsten Hothorn, Frank Bretz and Peter Westfall (2008), Simultaneous Inference in General Parametric Models. *Biometrical Journal*, **50**(3), 346--363

```
library(multcomp)
post <- glht(mod1, linfct = mcp(medium = "Tukev"))</pre>
summary(post)
       Simultaneous Tests for General Linear Hypotheses
Multiple Comparisons of Means: Tukey Contrasts
Fit: lm(formula = diameter ~ medium, data = culture)
Linear Hypotheses:
                                           Estimate Std. Error t value Pr(>|t|)
                                                        0.4143
with sugar - control == 0

                                                                        0.91168
with sugar + amino acids - control == 0 1.3310
                                                       0.4143
                                                                 3.212
                                                                       0.00912 **
with sugar + amino acids - with sugar == 0 1.1610
                                                       0.4143
                                                                 2.802
                                                                       0.02442 *
Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
(Adjusted p values reported -- single-step method)
```

#### Assumptions - exactly as stage 1

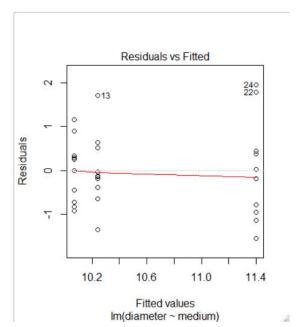

```
shapiro.test(mod1$residuals)
```

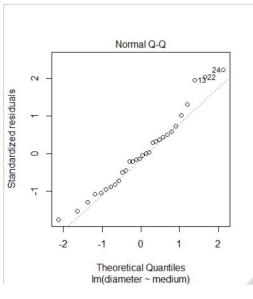

Shapiro-Wilk normality test

data: mod1\$residuals
W = 0.96423, p-value = 0.3953

plot(mod1)

These look fine

#### Key points

T-tests, ANOVA and regression are fundamentally the same, collectively called 'general linear models'. They can be carried out in R with Im()

The concept can be extended to 'generalised linear models' for different types of response. Generalised linear models are carried out in R with glm()

The output of Im() looks more complex, at first, than the outputs of t.test() and aov()

The output of glm() is like that for lm(). So we will revisit regression, t-tests and ANOVA using lm() to help you understand the output
